

Moving Cows

When moving cows, be gentle and quiet.
If cows are hurt, frightened or hurried,
milk letdown may be disturbed.
Look for and report sick cows!

Wear Gloves

Clean, dry healthy hands minimize the
spread of mastitis-causing organisms.
Wear nitrile or latex gloves to minimize the
surface area where bacteria can hide.

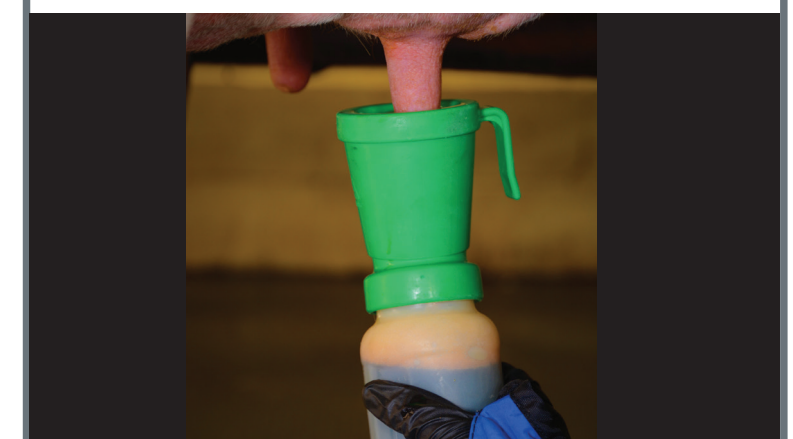

Forestrip

Identify signs of mastitis. 2-3 squirts of
milk should be squirted on the floor for
evaluation. Be gentle and make sure each
quarter is in good condition.

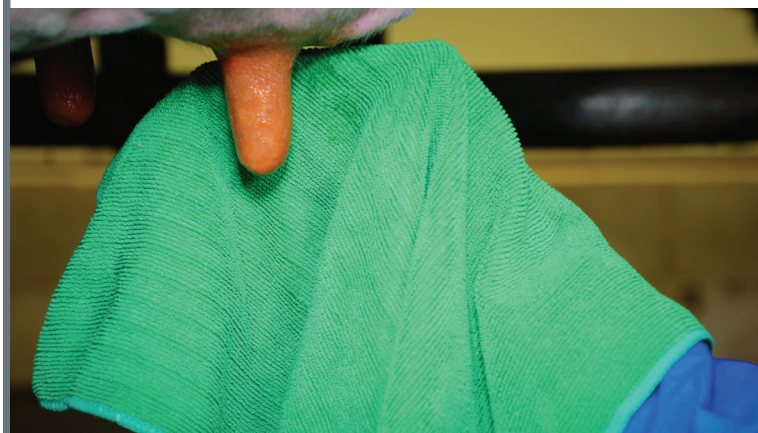

Pre-Dip

Use dip, foam or complete spray.
Cover the entire teat with sanitizer.
Pre-dip should remain in contact with the
teat for 20-30 seconds.

Clean and Dry

Gently remove soil and disinfectant in
a downward circular motion. Flip the
towel over and re-wipe teat ends.

Attach Milking Cluster

Attaching machines within 60-120 seconds
after first stimulation will maximize milk
letdown time. Make sure units are aligned
squarely with the base of the udder.

Post-Dip

With a good-quality dip, cover each
individual teat. This encourages a reduction
of bacteria growth by flushing off the milk
film left on the teat, improves skin condition
and seals teat ends.
